Pest management is often associated with controlling common household pests in residential settings. Depending on the type of infestation, pests can compromise a building’s structural stability and can even put property at risk for fire. However, the importance of the industry to the nation is much broader than controlling pests in the home. It plays a vital role in protecting our food supply and public health. In fact, public health officials attribute the quality of life we have today to three things: better pharmaceuticals and vaccines, better sanitation and better pest control.

PUBLIC HEALTH

- Pests contaminate food, as well as kitchen equipment and other surfaces. Pests also infest food items and stored products including grains and dry goods.
- Pests can spread diseases such as Zika virus, West Nile virus, Lyme disease, malaria, plague, Rocky Mountain spotted fever, hantavirus and encephalitis.
- Ninety-seven percent of allergists believe a pest-free home is an important step in preventing asthma and allergy symptoms.¹
- Seventy percent of homeowners with regular professional pest control service have it because it best protects their home and family.²
- Innovations in pest management parallel an increase in life expectancy. In 1900, life expectancy was just 49 years and in 2012 life expectancy rose to 78.8 years.
- It would be difficult to find any segment of the food industry that could comply with federal sanitation and health regulations without an adequate pest management program.

INDUSTRY OVERVIEW

19,586 COMPANIES
135,510 SERVICE TECHNICIANS
$8.9+ BILLION IN ANNUAL BILLING

MOSQUITOES

The mosquito is by far the most dangerous animal in the world, killing more people each year than humans, snakes and sharks combined. Mosquitoes are vectors of numerous diseases including malaria, dengue fever, yellow fever, encephalitis, chikungunya, West Nile virus and Zika virus.

Prevention around the clock is vital to reduce contact with mosquitoes and the spread of mosquito-borne illnesses.

BED BUGS

Bed bug bites can leave behind itchy, red welts and can increase one's risk for a secondary infection from scratching.

Nearly one hundred percent of pest professionals have treated for bed bugs in the past year. A majority of them say overall bed bug service work and the prevalence of these pests are increasing.5

The top three places where pest professionals report finding bed bugs are single-family homes, apartments/condominiums and hotels/motels.5

Bed bugs may be easily confused with other pests as most pest control professionals were initially contacted about a different type of pest, such as fleas, before correctly identifying them as bed bugs.5

TICKS

Ticks are vectors of Lyme disease, Rocky Mountain spotted fever, anaplasmosis, babesiosis and ehrlichiosis.

Ticks typically require 24-48 hours of feeding before they can successfully transmit diseases. If ticks are removed within the first 24 hours, infection is unlikely.

The appearance of a “bull's-eye” rash is often the first sign of Lyme disease. It occurs in about 70 to 90 percent of cases.

TERMITES

Termites are known as “silent destroyers” due to their ability to chew through wood, flooring and even wallpaper undetected.

Termites alone cause over $5 billion in property damage annually, a cost typically not covered by homeowners’ insurance policies.

Subterranean termites eat 24/7, making them the most destructive termite species found in the United States.

RODENTS

Rodents consume or contaminate about 20 percent of the world’s food supply.

Rats transmit diseases such as Salmonella, Rat-bite fever, hantavirus trichinosis, murine typhus, plague and Leptospirosis.

Rodents have been implicated in fires across the country by chewing wires and spilling flammables.

More than one-third of American homeowners (37 percent) have seen a rodent in their home in the past year.3

The top three places rodents are spotted in a home include the garage, kitchen and basement.3

STINGING INSECTS

Stinging insects send more than half a million people to the emergency room every year.

More than two million Americans are allergic to stinging insects.4

At least 50 people die each year as a result of insect stings.4

COCKROACHES

Cockroaches are known to spread 33 kinds of bacteria, including E. coli and Salmonella, six types of parasitic worms and seven kinds of human pathogens.

The saliva, droppings and decomposing bodies of cockroaches contain allergen proteins known to trigger allergy and asthma symptoms, especially in children.

Cockroach suppression and eradication is vital to healthcare
